NOTE.—For complete list of publications of the Indian Meteorological Department, see the covers of Monthly Weather Reviews prior to January 1909, or the lists bound up with the Annual Summaries from 1908 onwards.

CORRELATION IN SEASONAL VARIATIONS OF WEATHER VI.

Sunspots and Pressure.

The effect of sunspots on pressure has been discussed by H. A. — Blanford† and Hann;‡ but the data handled were somewhat limited and it cannot be claimed that any general result has been completely established. Fairly good evidence was however given by Blanford for the view that at times of many sunspots the pressure in the Hindomalay region is high, while that in European Russia and western Siberia is low. His suggestion for the explanation was that at such times the Indian rainfall is more abundant, and consequently that air is light and rises in greater quantities there, descending as dry air where the production of water vapour is a minimum, *i.e.*, in the cooler regions of the moderate zones, especially where a cold dry surface of land is quickly losing heat under a clear winter sky.

2. In the following paper the data are, for the reasons previously given,§ for the most part limited to years subsequent to 1850, as well as to the data of single stations. The pressures have in cases that appeared doubtful been plotted and compared with those of neighbouring stations excepting those extracted from Hann's classical table in Penck's *Geographische Abhandlungen*.|| In certain cases, especially where aneroid barometers were in use, it has been found that the earliest records showed departures from normal very much larger than those of years of reliable data, and in such cases the data have been rejected for present purposes.

The data are given in Table II, the correlation co-efficients in Table I, and the latter are charted in the accompanying plate.

With the object of facilitating verification the data in Table II are given with as little change as possible from the data in the tables from which they are compiled. If the originals are not reduced to constant gravity they are not reduced in Table II. If the originals are not reduced to sea level and changes have occurred from time to time in the altitudes of the barometers above sea level, the data of Table II have been reduced to the present altitude; thus in the Russian data the actual changes in altitude due to removals have been allowed for, but not the apparent changes due merely to fresh determinations of the height above sea level.

§ See Correlation in seasonal variations of weather IV, page 18.

|| 'Die Vertheilung des Luftdruckes'. Band II, Heft 2. Wien. 1887. I do not consider that Brückner has made out a strong enough case for altering Hann's data of Stykkisholm and Barnaul. See the remarks on pages 197-8 of his *Klimaschwankungen*. It appears to me from a comparison of Stykkisholm with Jacobshavn, Thorshavn and Greenwich that Stykkisholm was low between 1890 and 1900 to an average extent comparable with that from 1850 to 1866, also there is no sudden discontinuity between 1865 and 1866. In the case of Barnaul I have relied on a comparison of its curves with those of Lwiscisk, Irkutsk and Nikolaevsk, as well as of Ekaterinburg and Nertchinsk.

3. It would be premature to attempt a complete discussion of the causes that produce the pressure relationships until the data of certain other elements have been analysed, especially those of sunspots with the meteorological elements in summer and winter; but it may be of interest to make a preliminary survey of the chief features.

4. It is a striking fact that the region of negative co-efficients extends from India over a considerable area, including northern Africa, east and south Africa, Arabia, Persia, Java and Australia. Europe, except in its most southern districts, Siberia, the China coast and Japan appear to have positive co-efficients. As might be expected from the opposition in pressure between the Argentine or Chili and India the co-efficients in the former countries are strongly positive; and in the east coast districts of North America positive co-efficients prevail, though in the west there is a tendency towards negative values. In the Pacific (e.g., Honolulu and Wellington) the relationship appears to be generally positive, but in the Atlantic there is a negative region including Iceland, Scotland and the North Sea.

A comparison of the chart with the corresponding chart in a previous paper for sunspots and rainfall will bring out the general tendency for the pressure co-efficients to be opposite in sign to rainfall co-efficients; and it may be inferred that the variations of pressure and rainfall are to a large extent dominated by the same cause, being to a comparatively small extent affected by variations of temperature. For instance in the Argentine and Chili both pressure and rainfall are opposite in their relations with sunspots to those of India, while temperatures in all these regions have the same marked negative relationship. From this last too it may be inferred that the relationship between sunspots and temperature is brought about rather by excess of humidity in the air, at any rate in its higher levels, than by excess of rain. In coast regions with tendency at times of maximum sunspots to diminished pressure and increased rain the natural explanation lies in an increased flow of moist air from sea to land.

5. As was pointed out by Brückner in his *Klimaschwankungen** we should expect an increase of solar radiation to be associated with a fall of pressure in equatorial regions and a rise in those areas where the air descends that has ascended near the equator. In other words we should expect an accentuation of those features which are due to the sun's heating. If we consult a chart of annual isobars of the world† we may pick out as the chief of these features:—

- (a) A fall in the equatorial regions including India.
- (b) A fall near Iceland and the Aleutian Islands.
- (c) A rise near Honolulu, the Azores, and central Siberia.
- (d) A rise in the south Indian Ocean, the south Atlantic and south Pacific, in all three cases about latitude 30°.

* Page 239.

† See for instance Plate 11 in Bartholomew's *Atlas of Meteorology*.

When examining the blue shading on the correlation chart it must be remembered that this has been drawn on a purely geometrical consideration of the comparatively few stations available, without any straining towards a physical interpretation. It will then be seen that (a) holds for the eastern hemisphere, and may hold partially at any rate in the western. Of (b) the first half holds; there are no data for the Aleutian Islands. Of (c) the first two hold, but the rise in Siberia does not extend far enough south. Of (d) the rise in the south Pacific appears on the chart but instead of that in the south Atlantic and India oceans we have indications of a fall. Thus the chief discrepancy lies in a fall over a larger area than might be expected in the southern half of the eastern hemisphere. If 15 were added to the co-efficients of the eastern hemisphere and subtracted from those of the western the general agreement would be improved.

Associated with a rise of pressure at the Azores and fall in Iceland there is known to be a rise of temperature in northwest Europe with more rain, at any rate in winter; and these two features are shown on the corresponding charts.

6. Among the areas most conspicuous for increases of rain with sunspots will be found, in addition to northwest Europe, India, the north and east coast districts of Australia which form the area of their summer monsoon rains, the northwest of the United States, the west coast of northern Africa, and the eastern districts of south Africa. Considering first the India monsoon rains, which are brought by moist winds from the Indian Ocean it is interesting to note that these are associated with less rain in that ocean and a stronger gradient between the ocean and India: Similarly the increase of Australian rain is probably associated with a decrease of rain in the seas to its north and an increase of gradient from the Chinese seas and the Philippines to Australia. The increase of rain in the northwest of the United States also is accompanied by a decrease of rain in the north Pacific as represented by Honolulu and an increase of gradient thence to the land. The cases of increased rainfall in Africa may also be associated with increased gradients, but here data are lacking.

These cases cannot be regarded as satisfactorily explained until the statistics for summer and winter have been separately calculated, but they at any rate lend support to the interpretation in terms of increased radiation.

7. Among the difficulties left unexplained is the tendency in the Mediterranean and Syria towards diminished rainfall in spite of diminished pressure. But as in this area the rainfall occurs mainly in the winter months it may be that the features of pressure at that time are masked by the features during the rest of the year.

8. Perhaps I may be permitted to express the hope that as opportunities occur, the weather departments of the different countries will prepare and print collections of revised monthly data of pressure, temperature and rain for all their chief observatories. In many cases they can form a better idea than an outside department of the extent to which observations are reliable, and it is much better that authoritative tables should be published once for all rather than that each investigator should have to prepare his own tables. I believe that methods of seasonal forecasting can only be developed on the bases of a statistical examination of the past monthly and annual data; and progress will be very greatly facilitated if these verified collections are made easily accessible.
